Preface

In late 1976 a study to produce a wave climate for U.S. coastal waters was initiated at the U.S. Army Engineer Waterways Experiment Station (WES). The Wave Information Studies (WIS) was authorized by Headquarters, U.S. Army Corps of Engineers (HQUSACE) as part of the Coastal Field Data Collection Program, which is managed by the WES Coastal Engineering Research Center (CERC). Mr. John H. Lockhart, Jr., Mr. Charles B. Chesnutt, and Mr. Barry W. Holliday, HQUSACE, are Technical Monitors for the Coastal Field Data Collection Program. Ms. Carolyn M. Holmes, CERC, is Program Manager and Dr. Jon M. Hubertz, CERC, is WIS Project Manager.

This report, the 33rd in a series, provides additional wave information, which includes hurricane data, for 108 nearshore stations along the U.S. Atlantic coastline. This data tabulation is a continuation of the data presented in WIS Report 30. The period of record for this hindcast update is the 18 years from 1976 through 1993. The information was derived using wind fields from the U.S. Navy Fleet Numerical Meteorology and Oceanography Center (FNMOC) in Monterey, CA, and the present version of the WIS wave model. This report was written by Ms. Rebecca M. Brooks and Ms. Willie Ann Brandon, CERC. Application of the model for the extratropical hindcast update, yearly verifications during production, and preparation of all tables and statistical calculations were done by Ms. Brooks. Ms. Brandon conducted the hurricane portion of this hindcast. Ms. Barbara Tracy, CERC, was responsible for preproduction model tests to assure proper functioning of the computer code. Dr. Hubertz provided supervisory guidance and technical assistance throughout the study. Ms. Jane M. Smith, CERC, restructured the post-production computer code which identified primary and secondary wave components from the model's spectral output. Dr. Norman W. Scheffner, CERC, provided the source code which created snapshots used in generating the tropical cyclone wind fields. Mr. Dennis Laws, FNMOC, is acknowledged for his assistance in providing the raw data from which the numerical model input wind fields were generated.

The study was conducted under the direct supervision of Dr. Martin C. Miller, Chief, Coastal Oceanography Branch (COB), CERC, and Mr. H. Lee Butler, Chief, Research Division, CERC, and under the general supervision of Dr. James R. Houston and Mr. Charles C. Calhoun, Jr., Director and

Assistant Director, CERC, respectively. Ms. Mary Guzzo, Computer Science Corporation, assisted with the word processing of this report. Non-technical editing of this report was done by Ms. Janean Shirley, Information Technology Laboratory, WES.

At the time of publication of this report, Dr. Robert W. Whalin was Director of WES. COL Bruce K. Howard, EN, was Commander.

The contents of this report are not to be used for advertising, publication, and promotional purposes. Citation of trade names does not constitute an official endorsement or approval of the use of such commercial products.

Conversion Factors, Non-SI to SI Units of Measurement

Non-SI units of measurement used in this report can be converted to SI units as follows:

Multiply	By	To Obtain
inches	2.54	centimeters
knots (international)	0.514444	meters per second
miles (U.S. nautical)	1.852	kilometers

1 Introduction

Background

Wave Information Studies (WIS) have supplied wave climate information at nearshore locations along the U.S. Atlantic coast for the 20-year period 1956-1975, documented in WIS Report 2 (Corson et al. 1981), WIS Report 6 (Corson et al. 1982), and WIS Report 9 (Jensen 1983). This met a critical need for wave information in coastal engineering studies in the 1980's. Wave measurements which the National Oceanic and Atmospheric Administration (NOAA) recorded during the 1980's made verification of these WIS results possible by comparing statistics and the distributions of wave heights, periods, and directions from the two different time periods (1956-1975 and the 1980's). The statistics and distributions differed enough (Miller and Jensen 1990) that the original 1956-1975 hindcast for the Atlantic Coast was revised using an updated version of the WIS numerical wave model and a nested latitude-longitude grid system. The revised 20-year wave information published in WIS Report 30 (Hubertz et al. 1993) supersedes all previously published wave data for the Atlantic coast.

A separate study was conducted to produce hindcast wave information for Atlantic coast hurricanes during the 1956-1975 time period. These data, published in WIS Report 19, were referenced to the same spherical orthogonal grid as the original WIS extratropical hindcast (Abel et al. 1989). It should be noted that the Atlantic hindcast revision excludes tropical storms and hurricanes (Hubertz et al. 1993). As noted in WIS Report 4, hurricanes were not included due to the complexity and diversity of shapes, intensities, and internal structures of these storms (Resio, Vincent, and Corson 1982). Therefore, for the years 1956 through 1975 there are two separate databases referenced to two different grid systems. Hence, there was a definite need to include tropical storms and hurricanes in the update hindcast for the Atlantic coast.

Objective

In order to provide wave information along the Atlantic coast for an extended period of record, an update hindcast for an additional 18 years

(1976-1993) was performed using the U.S. Army Engineer Waterways Experiment Station (WES), Coastal Engineering Research Center's (CERC) directional spectral wave hindcast model. This model, an updated version of WISWAVE 2.0 (Hubertz 1992), is hereafter referred to as WISWAVE. To better represent a realistic wave climate, tropical storms and hurricanes were included in the 1976-1993 hindcast. This study is the first time WIS has produced an Atlantic coast wave climate database which combines tropical cyclones and extratropical events.

Selection criteria for tropical cyclones to be included in the hindcast were based on historical data regarding their storm track proximity to the Atlantic coast. To be selected, the tropical cyclone had to be at least a tropical storm. A tropical storm is defined as a tropical cyclone with winds stronger than 27 knots¹ but less than 64 knots. A hurricane is defined as a tropical cyclone whose wind speeds are 64 knots or greater. Usually, when a tropical cyclone reaches hurricane status, a well-defined eye has been formed. For purposes of this report, the term **tropical cyclone** refers to both tropical storms and hurricanes. All wind fields other than tropical cyclones are described as **extratropical**. Due to project time constraints, the only cyclones analyzed with any detail were the tropical cyclones.

This report summarizes the procedures used in the update hindcast and the yearly verifications for both the extratropical and tropical cyclone production calculations. These merged hindcast results, including annual statistics, are presented in Tables 3-9 and in the summary tables in Appendices A and B.

¹ A table of factors for converting non-SI units of measurement to SI units is presented on page vi.

2 Computational Grids

The computational grid for a numerical model application must be defined such that the topographical variations are well represented. The size of the grid cells, in terms of degrees, and the geographical placement of the grid are important, since the combination of these two criteria defines the area of interest for the study and affects the study results.

The selection of the grids was based on the grids used for the Atlantic revision as described in WIS Report 30 (Hubertz et al. 1993). The level 1 and level 2 grids used in the Atlantic revision are shown in Figures 1 and 2. The grids used for the Atlantic update are also latitude-longitude grids with 1.0-deg and 0.25-deg resolutions, respectively. These grids are shown in Figures 3 and 4.

Latitude-longitude grids were used in running both the wind and the wave models. Propagation along meridians (or components of propagation along meridians) is the equivalent of propagation along great circles. Consequently, there is no curvature away from a straight-line propagation along these axes; however, divergence/convergence effects must be incorporated for meridional propagation. For propagation along latitudes (parallels), there is no divergence/convergence; but, there is angular curvature that must be considered.

For this study, a 60-n.m. grid which covered the entire north Atlantic Ocean was used for level 1 (Figure 3). This grid covered the same geographical area as the level 1 grid used in the revision. That is, level 1 extends from latitude 10°N to 65°N and from longitude 5°W to 82°W. The southern input boundary points of the level 1 grid were introduced in the update study to allow for tropical cyclones approaching from the south. All water depths in the computational grid area for level 1 were considered to be deep water and were represented with a standard depth of 999 m.

To obtain better resolution of the coastline, a 15-n.m. grid covering the continental shelf area was used for level 2 (Figure 4). This level 2 grid begins at latitude 22.75°N and extends to 45.25°N and from longitude 64.75°W to 81.5°W. The size of the computational grid for level 2 was enlarged in the update hindcast to allow for spatial resolution of hurricanes. Also, the additional water points in the land-sea matrix of the model allowed

better definition of the study area. As in the previous Atlantic hindcast, the Bahamas Banks and shoals off the southeast coast of Florida were included in the model's depth grid. Bathymetric data used for the level 2 grid were recorded at mean low water.

3 Numerical Model Input Winds

Extratropical Wind Fields

Winds over the ocean surface are the primary driving mechanism for generating waves via a numerical spectral wind-wave growth model. The surface wind fields used as input for the original Atlantic coast hindcast were calculated from atmospheric pressure fields, assimilated observations of wind speeds from ships, and a parameterized boundary layer wind model (Resio, Vincent, and Corson 1982). Since these wind fields were referenced to a spherical orthogonal grid, an interpolation scheme was applied to obtain wind fields referenced to the latitude-longitude grid used for the 1956-1975 revised Atlantic coast hindcast (Hubertz et al. 1993).

For continuity in the 1976-1993 Atlantic update hindcast, WIS used similar latitude-longitude grids as in the revision (Figures 1-4), but discarded the historical approach used to generate the earlier wind fields. Recent significant advances in atmospheric modeling capabilities and operational numerical models have made both historical and near real-time wind products available on global grids (Demirbilek, Bratos, and Thompson 1993).

It was advantageous for WIS to obtain products related to surface winds from the U.S. Navy Fleet Numerical Meteorology and Oceanography Center (FNMOC) in Monterey, CA. The Navy's global numerical weather prediction is based on the Navy Operational Global Atmospheric Prediction System (NOGAPS). NOGAPS is a global spectral model which produces output fields on grids with 2.5-deg and 1.25-deg horizontal resolution (Hogan and Rosmond 1991). The wind product WIS used for this update hindcast was generated on the NOGAPS 2.5-deg "global_73x144" spherical projection grid (Figure 5). Global wind fields in terms of U-V wind components at 19.5-m elevation for the period 1976-1993 were obtained from FNMOC and archived by WIS. For reference purposes, FNMOC identifies these 6-hr wind fields with the label A29/A30.

Beginning in 1993 and working backwards, each month and year of the A29/A30 data set was processed and checked to assure that the wind components were continuous in time. For the occurrences when the time gaps in the data were less than 10 consecutive 6-hr intervals, a proportional linear

temporal interpolation scheme was utilized to fill in the time series. In 1976, when as much as 2 weeks of data were missing and it was not feasible to use this approach, the wind data were supplemented with data from another source. Specifically, WIS used wind data from the National Meteorology Center to augment the data from FNMOC.

Since the areas of interest for this update study are the north Atlantic Ocean (level 1) and the U.S. east coast (level 2), as described in Chapter 2, a subsection of FNMOC's 2.5-deg global grid was extracted prior to applying the bilinear algorithms used in the spatial interpolation schemes. Two separate routines, one for each of the hindcast grids, were used to calculate values for the U and V wind components. The final wind generation program used these components to produce the 6-hr input wind fields required for the numerical hindcast model. These 6-hr winds were interpolated in time to create the 1-hr wind fields needed as background winds in the tropical cyclone hindcast.

Tropical Cyclones

The National Hurricane Center (NHC) maintains a computer file for North Atlantic tropical cyclones. This file contains the dates, tracks, wind speeds, and central pressure values, if available, for all tropical cyclones which occurred from 1886 to the present. These data are available on magnetic tape at 6-hr intervals recorded at 0000, 0600, 1200, and 1800 UTC. This database is updated annually and is called the HURricane DATa (HURDAT) tape (Jarvinen, Neumann, and Davis 1984). Information from this HURDAT tape was used as input to a source code written by Dr. Norman W. Scheffner, CERC. This code created representative snapshot storm parameters used in generating the tropical cyclone wind fields.

To better define each of the tropical cyclones, various weather reports were used to obtain any additional information available, which could be used to supplement the data from the HURDAT tape. In some instances, more information was available along the storm track. Sometimes the minimum pressure outside the 6-hr intervals recorded on the HURDAT tape was available. Occasionally, the pressure at landfall was quoted.

The tropical cyclone winds for the wave hindcast were modeled using a system of programs called HURWIN (Thompson 1993). These source codes generated 1-hr winds from the snapshot parameters. Details on the numerical model are documented in Cardone, Greenwood, and Greenwood (1992). This system contains an efficient numerical scheme to solve the equation of horizontal motion vertically averaged through the depth of the Planetary Boundary Layer (PBL) for a tropical cyclone, written in coordinates fixed to the earth as:

$$\frac{d\hat{V}}{dt} + \bar{f}\bar{k} \times \hat{V} = -\frac{1}{\rho}\nabla p + \nabla \cdot (K_H \nabla \hat{V}) - \frac{C_D}{h}|\hat{V}|\hat{V} \quad (1)$$

where

$$\frac{d}{dt} = \frac{\partial}{\partial t} + \hat{V} \cdot \nabla;$$

\times = vector or cross product (vector multiplication)

\cdot = dot or scalar product (vector multiplication)

$\frac{\partial}{\partial t}$ = time change local to the fixed coordinates

$\nabla = \frac{\partial}{\partial x} + \frac{\partial}{\partial y}$ = two-dimensional del operator

\hat{V} = vertically averaged horizontal velocity

f = Coriolis parameter

\bar{k} = unit vector in the vertical direction

ρ = mean air density

p = combined central pressure of the storm and the geostrophic flow

K_H = horizontal eddy viscosity coefficient

C_D = drag coefficient

h = depth of the planetary boundary layer

The PBL model allows for the calculation of transformations for a maximum of six terrain categories (Cardone, Greenwood, and Greenwood 1992). Several tests were conducted to determine if a mixed terrain grid would have an effect on wind and wave results. Based on comparisons to measured data, these tests showed that the results were better with a mixed terrain grid. Therefore, to better represent real data, a mixed terrain grid was used to calculate the tropical cyclone winds for both grid levels. Once these PBL winds were calculated, level 1 background winds were added to produce a smooth wind field. This "blending" process, which merged the PBL-modeled winds with the winds generated from FNMOC's global wind

components, created the final winds needed for the level 1 tropical cyclone hindcast.

The 1.0-deg blended wind fields described above were bilinearly interpolated to produce winds on the 0.25-deg grid, which were then used as the background winds for level 2. Next, level 2 tropical cyclone winds were modeled by HURWIN and blended into these interpolated winds. The final level 2 tropical cyclone wind fields were compared to measured data to determine their accuracy. If the differences between the two data sets showed bad comparisons, the input was analyzed to determine if any input parameters needed changing (i.e. radius, pressure, etc.). Based on literature reports, parameters such as radius of maximum winds, far field pressure, or minimum pressure were adjusted and a new set of wind fields was generated and compared to the measured data. After verification, these wind fields were then used as input for WISWAVE. It should be noted that the final blended wind fields have a temporal spacing of 1 hr for both grids. These 1-hr winds were used for the tropical cyclone model applications, since they represent actual hourly tropical cyclone conditions.

4 WIS Hindcast 1976-1993

Numerical Wave Model

The model WISWAVE is based on the assumption that the wave field on a water body can be represented by a distribution of energy in discrete frequency and direction elements. The change in energy in each element as a function of time at all specified points on the water body is determined by the radiative transfer equation (Resio and Perrie 1989):

$$\frac{\partial E(f, \theta)}{\partial t} = \bar{c}_g(f) \cdot \nabla E(f, \theta) + \sum_{i=1}^N S_i \quad (2)$$

where

$E(f, \theta)$ = energy density at frequency f and propagation direction θ
 \bar{c}_g = group velocity vector for that frequency-direction element
 S_i = source/sink mechanism

WISWAVE is a computer code that simulates the growth, propagation, and decay of wave energy as a function of space, time, frequency, and direction. Wave growth occurs through transfer of energy from the wind to the sea surface.

The model has the option to employ nested grids of finer resolution to more closely approximate land-water boundaries and bathymetric features near sites of interest. Also, the propagation routines and source functions in WISWAVE have the capability to utilize arbitrary depths.

Hindcast Wave Data

Both the tropical cyclone and extratropical production calculations were run on the CRAY C90 supercomputer in the WES High Performance Computing Center, Information Technology Laboratory. The nested grid option was employed using two levels of resolution, as discussed in Chapter 2. The circled points in Figure 3 represent level 1 grid points which supply boundary information to the level 2 grid. For this update hindcast, the level 1 boundary

points needed for level 2 are located along the eastern and southern edges of the level 2 grid (Figure 4). Level 2 grid points between the coast and the boundary input points from level 1 are computational water points with associated depths.

This WIS update was accomplished by conducting two separate hindcast studies, both applying WISWAVE. The extratropical portion of the study used 3-hr wind fields generated from FNMOC global wind components via temporal and spatial interpolation routines. However, it was necessary to use hourly input winds for the tropical cyclone simulations to ensure proper modeling of the storm peaks. These 1-hr blended wind fields were assimilated from NHC data, national weather sources, and the HURWIN system of programs. After production, the 1-hr tropical cyclone data were merged with the 3-hr hindcast wave data.

The results of this update hindcast are intended to be a continuation of the data from the revised 20-year hindcast, therefore, the model output stations are the same as those published in WIS Report 30 (Hubertz et al. 1993). These model output stations are shown in Figure 6 as numbered dots along the east coast of the United States. The latitude-longitude coordinates for each location and its associated water depth are listed in Table 1. Hindcast wave information, including the effects of tropical cyclones, is available every 3 hr for each of these stations from 1976 through 1993.

5 Verification and Statistics

After each year of wave data was calculated, extensive comparisons and time history plots were produced as an intermediate verification of the results. These statistics and plots provided a continuous check regarding the accuracy and reliability of the resultant model data.

The measured data used in the comparisons were retrieved from CERC's Coastal Engineering Data Retrieval System (CEDRS) library archive. These buoy data and Coastal-Marine Automated Network (CMAN) data were obtained by CEDRS personnel from NOAA's National Data Buoy Center, Stennis Space Center, MS.

Figure 7 shows the locations of the Atlantic NOAA buoy and CMAN stations that recorded wave data during the hindcast period. Their latitude-longitude coordinates and water depths are listed in Table 2. Statistical analyses were performed for any time frame for which measured data were available. However, due to the sparseness of the measured data prior to 1980, this report summarizes the statistical results for the years 1980 through 1993. If no value is tabulated for a particular buoy and year, there were no measured data available for comparisons. Tables 3 through 9 present the following annual statistics:

$H_{mo} RMSD$ = wave height root mean square difference

$T_p RMSD$ = peak wave period root mean square difference

$H_{mo} Bias$ = wave height bias

$T_p Bias$ = peak wave period bias

N = number of occurrences compared for the statistics

r = wave height correlation

r = peak wave period correlation

where

H_{mo} = spectrally based wave height

T_p = peak wave period

W = WISWAVE hindcast data

M = NOAA buoy/CMAN measured data

$$RMSD = \sqrt{\frac{1}{N} \sum_{i=1}^N (W_i - M_i)^2} \quad (3)$$

$$Bias = \bar{W} - \bar{M} \quad (4)$$

$$r = \frac{\sum_{i=1}^N (M_i - \bar{M})(W_i - \bar{W})}{\sqrt{\left(\sum_{i=1}^N (M_i - \bar{M})^2\right) \left(\sum_{i=1}^N (W_i - \bar{W})^2\right)}} \quad (5)$$

and $Mean = \bar{X} = \frac{1}{N} \sum_{i=1}^N X_i$ for either WISWAVE or NOAA data.

The standard deviation about the mean was calculated for both wave height and peak wave period. These results, provided in the summary tables (Appendix A), are defined as:

$$\sigma = \sqrt{\frac{1}{N-1} \sum_{i=1}^N (W_i - \bar{W})^2} \quad (6)$$

Table 10 presents comparisons of the statistical results from the Atlantic revision¹ and the Atlantic update hindcasts for the year 1990. The 0.0 and -0.0 listed in the table are not true zeros, but represent very small numbers. That is, a value of -0.0 represents a number between 0.0 and -0.04, and 0.0 indicates a number between 0.0 and 0.04. Figures 8 through 11 show comparison plots of wave height, wave period, wind speed, and wind direction for 4 of the 14 buoys listed in Table 10. These buoys (44011, 44008, 44004, and 41001) recorded data during 1990 and are located in the

¹ In conjunction with the 1956-1975 revised Atlantic hindcast, a 1-year hindcast for 1990 was done for verification purposes (Hubertz et al. 1993). The input winds for this study were generated from FNMOC's global wind components, but tropical cyclones were not modeled and blended into these wind fields.

proximity of the storm track of Hurricane Lili (Figure 12). Hurricane Lili was a tropical cyclone in the north Atlantic that occurred from 11 October 1990 until 15 October 1990.

The verification results presented in Table 10 indicate that the update hindcast for 1990 provides a better representation of the wave climate than the revised hindcast. The wave heights, periods, and wind speeds and directions from the Atlantic update show a closer approximation to measured data (Figures 8-11). These results are somewhat higher than actual observations, but better than those from the earlier hindcast. The improved results are attributed to the present version of WISWAVE and the inclusion of tropical cyclones in the wind fields. Figures 8 through 11 show good comparison between tropical cyclone results and measured data for 1990. Therefore, the Atlantic update wind and wave information is judged to be representative of measured conditions.

6 Results

Hindcast results from 1976 through 1993, which include the effects of tropical cyclones, are available for the 108 stations shown in Figure 6. Wave results are available as digital time series or as tabulated summaries (Appendix A). Each record of the time history contains the WIS station number, date-time identifier (UTC), spectrally based wave height (m), peak and mean wave periods (sec), mean wave direction (deg "from" in a compass sense), wind speed and wind direction (m/sec, same directional convention as waves), the frequency spectrum (percentage of m^2/hz), and the mean direction in each frequency band (percentage of 360 deg). This record format was designed to provide basic wave information such as wave height, period, and direction, as well as a more complete spectral description of wave conditions. The format and documentation of these output records are described in detail in WIS Report 27 (Hubertz 1992), or in a text file, when individual station data are provided on diskette. The 1976-1993 time series for one station can be provided in a compressed format on two high-density 3½-in. disks for use on personal computers. Approximately 7 MB of disk space is required to restore the entire 18-year data file for one station, if formatted as described above.

WIS used the computer code SPEctral COMPOnents (SPECOMP), written by Ms. Jane M. Smith, CERC, to post-process each station's spectral file output from WISWAVE. This program determines the two major components in frequency and direction of the directional spectra. This alternate format is useful when an application requires better resolution of directional spectral wave energy than the resolution possible using only the spectral height, peak period, and peak mean direction, but still confining the information to triplets of height, period, and direction. Each station's 18-year component file, with accompanying documentation, can be provided in a compressed format on one high-density 3½-in. diskette. Less disk space, approximately 4 MB, is required to restore a component data file for one station. Time series of results, in either format, and tabulated statistical summaries are available. For more information, contact the WIS project office (601-634-2028).

7 Explanation of Summary Tables

The 1976-1993 hindcast wave results are summarized and tabulated in a 4-page format for each station. These summary tables are presented in Appendix A. The first page contains the distribution of spectral wave height, peak period, and peak mean direction in 0.5-m height, 1-sec period, and 22.5-deg direction categories by month for the 18-year period. These tables are useful in showing the distribution of height, period, and direction through the range of their values and in time through the year. As an example of using this table, at station 1 (page A-3) for all Januaries from 1976 to 1993, inclusive, there were 2,120 occurrences of hindcast waves with a height between 0.50 and 0.99 m, inclusive. The total number of possible occurrences for each month is shown at the bottom of each monthly column. The total for February differs from the other months due to the length of the month (28 days), plus an extra day in the month every 4 years, or leap year. The total number of occurrences in each category is shown in the last column on the right side of the page. Since there are 18 years of data at 3-hr intervals, the total possible number of occurrences is 52,600. As in WIS Report 30 (Hubertz et al. 1993), the *number* of occurrences is reported, rather than *percent* occurrences. The number of occurrences is used to explicitly account for each occurrence. The truncation of percentage values can omit indication of rare occurrences and possibly yield cumulative totals less than 100 percent.

The next set of tables shows the number of occurrences by 1-m height and 2-sec period categories for eight different direction bands, each 45 deg in width, and a final table for all directions. These tables are useful to find the dominant direction from which wave energy is approaching a location and how it is distributed in height and period. For example, at station 1 (page A-4), there were 133 occurrences of waves with a height between 2.00 and 2.99 m and period between 9.0 and 10.9 sec from the direction band between 67.50 and 112.49 deg centered about 90.0 deg. Height and period category summations are shown along the bottom row and right-hand column, respectively, as in the occurrences-by-month tables discussed above. Note at this station, there were 28,739 occurrences out of a total of 52,600 from directions between compass directions of ENE and ESE, and most of these are low in height and period.

The distribution of winds in 2.5-m/sec and 45-deg speed and direction categories, on a monthly basis, is shown in the next two tables. These tables are useful for understanding the climatology of winds at a particular site. Local sea conditions and wind-driven currents can be inferred from the wind climatology. At station 1, winds are generally less than 7.5 m/sec and are from the east or northeast.

The last two tables for station 1 (page A-6) summarize mean and maximum wave heights by month for each of the 18 years hindcast. The maximum wave height table also includes the peak period and peak mean wave direction associated with the maximum wave height occurrence. Means and maxima by month for all years, and by year for all months, are summarized on the bottom row and right-hand column, respectively. Associated peak periods and peak mean directions are included in the summary row and column of the maximum table.

As an example, the maximum wave height in 1976 at station 1 was 3.8 m, its associated peak period was 9 sec, and its associated peak mean direction was from approximately 90 deg. Since the peak directions in this table are divided by 10, the tabulated value is the mid-range of a 10-deg direction band. The actual value for the peak direction, represented by 9, could have been any direction from 85 to 94 deg. The largest wave height occurring at station 1 in any of the Januaries during the 18-year period was 5.8 m with an associated peak period of 10 sec and peak direction of 90 deg.

The last four lines of the summary tables for each station provide statistics for the entire 18-year period of record. Line 1 contains the maximum wave height, its associated peak period, associated peak mean direction, and date of occurrence. Line 2 contains the maximum wind speed, its associated wind direction, and date of occurrence. Overall mean wave height and mean peak period are given on line 3. The standard deviation about the mean for wave height and peak wave period are reported on line 4.

Appendix B contains estimated wave heights for return periods of 2, 5, 10, 20, 25, and 50 years based on the 18 years of hindcast results and the Fisher-Tippett Type I and Type II distributions. The values were calculated using the methods employed in the significant wave height analysis module of the Automated Coastal Engineering System (ACES) (Leenknecht, Szuwalski, and Sherlock 1990).

These summary tables and the model output records from which they were derived are a verified source of information for the wind and wave climate along the east coast of the United States. This information can be used to gain a basic understanding of wind and wave conditions at a particular site and also as input to more specific modeling associated with coastal engineering projects. Present coastal engineering practice requires site-specific investigations with possible alternative model applications. Thus, higher resolution wave information close to the shore is more efficiently produced, as required, making use of offshore wave information, such as provided by this

hindcast, rather than applying a higher resolution level of modeling along the entire coastline. The 1976-1993 hindcast results for the Atlantic coast, which include the effects of tropical cyclones, are a continuation of the 1956-1975 hindcast wave information summarized in WIS Report 30 (Hubertz et al. 1993).

12a. DISTRIBUTION/AVAILABILITY STATEMENT Approved for public release; distribution is unlimited.			12b. DISTRIBUTION CODE	
13. ABSTRACT (Maximum 200 words) <p>Eighteen years (1976-1993) of hindcast wind and wave information, including hurricanes, is summarized for 108 nearshore locations along the U.S. Atlantic coast. Procedures used to produce this information are discussed and examples of verification against measured data are presented. Tables for each station summarize occurrences by month of spectral wave height, peak wave period, peak mean wave direction, wind speed and wind direction for categories of 0.5 m, 1.0 sec, 22.5 deg, 2.5 m/sec, and 45 deg, respectively. Joint occurrences of height and period for 45-deg direction bands and all directions are tabulated. Finally, mean heights by month and year and maximum heights by month and year, with associated peak periods and peak mean directions, and overall statistics are shown. The 18-year time series of wind and wave information for each station, including spectra, is available from the WIS archive as one-line records every 3 hr. The data tabulation presented in this report is a continuation of the wave information summarized in WIS Report 30.</p>
